## 5 MARKS

1. Explain determination of Empirical Formula from Elemental Analysis Data.

* Step 1: Since the composition is expressed in percentage, we can consider the total mass of the compound as 100 g and the percentage values of individual elements as mass in grams.
* Step 2: Divide the mass of each element by its atomic mass. This gives the relative number of moles of various elements in the compound.
* Step 3: Divide the value of relative number of moles obtained in the step 2 by the smallest number of them to get the simplest ratio.
* Step 4: (only if necessary) in case the simplest ratios obtained in the step 3 are not whole numbers then they may be converted into whole number by multiplying by a suitable smallest number.

2. What is oxidation number? State the rules to find the oxidation number.

* It is defined as the imaginary charge left on the atom when all other atoms of the compound have been removed in their usual oxidation states that are assigned according to set of rules. A term that is often used interchangeably with oxidation number is oxidation state
* The oxidation state of a free element (i.e. in its uncombined state) is zero.

Example : each atom in $\mathrm{H}_{2}, \mathrm{Cl}_{2}, \mathrm{Na}, \mathrm{S}_{8}$ have the oxidation number of zero.

* For a monatomic ion, the oxidation state is equal to the net charge on the ion.

Example : The oxidation number of sodium in $\mathrm{Na}^{+}$is +1 .
The oxidation number of chlorine in $\mathrm{Cl}^{-}$is -1 .

* The algebric sum of oxidation states of all atoms in a molecule is equal to zero, while in ions, it is equal to the net charge on the ion.
* Hydrogen has an oxidation number of +1 in all its compounds except in metal hydrides where it has - 1 value.

Example: Oxidation number of hydrogen in hydrogen chloride $(\mathrm{HCl})$ is +1 . Oxidation number of hydrogen in sodium hydride $(\mathrm{NaH})$ is -1 .

* Fluorine has an oxidation state of -1 in all its compounds.
* The oxidation state of oxygen in most compounds is -2 . Exceptions are peroxides, super oxides and compounds with fluorine. Example : Oxidation number of oxygen in water $\left(\mathrm{H}_{2} \mathrm{O}\right)$ is -2 .
* Alkali metals have an oxidation state of +1 and alkaline earth metals have an oxidation state of + 2 in all their compounds.

\end{aligned}
$$

$\therefore$ to produce 10 moles of ammonia $=\frac{3 \text { moles of } \mathrm{H}_{2}}{2 \text { moles of } \mathrm{NH}_{3}} \times 10$ moles of $\mathrm{NH}_{3}$

$$
=15 \text { moles of hydrogen are required. }

$$
\mathrm{CH}_{4}(\mathrm{~g})+2 \mathrm{O}_{2}(\mathrm{~g}) \rightarrow \mathrm{CO}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g})
$$

As per the stoichiometric equation, Combustion of 1 mole $(16 \mathrm{~g}) \mathrm{CH}_{4}$ produces 2 moles $(2 \times 18=$ 36 g ) of water.

&=28.57 \mathrm{~g} \mathrm{Mg} .
\end{aligned}
$$

i.e. percentage of magnesium $=28.57 \%$.

$$
\begin{aligned}
& (24)+(12)+(3 \times 16)=84 \mathrm{~g} \mathrm{~mol}^{-1} \\
& \begin{aligned}

\end{aligned}
$$

$\therefore$ Percentage of carbon $=14.29 \%$.
$84 \mathrm{~g} \mathrm{MgCO}_{3}$ contain 48 g of oxygen

$$
\begin{gathered}
\therefore 100 \mathrm{~g} \mathrm{MgCO}_{3} \text { contains }=\frac{48 \mathrm{~g} \mathrm{o}}{84 \mathrm{~g} \mathrm{MgCO}} \times 100 \mathrm{~g} \mathrm{MgCO}_{3} \\
=57.14 \mathrm{~g} \text { of oxygen. }
\end{gathered}
$$

$\therefore$ Percentage of oxygen $=57.14 \%$.
As per the stoichiometric equation, 84 g of $100 \%$ pure $\mathrm{MgCO}_{3}$ on heating gives 44 g of $\mathrm{CO}_{2}$.
$\therefore 1000 \mathrm{~g}$ of $90 \%$ pure $\mathrm{MgCO}_{3}$ gives $=\frac{44 \mathrm{~g} \mathrm{o}}{84 \mathrm{~g} \mathrm{MgCO}} \times 90 \% \times 1000 \mathrm{~g}$
